#### Abstract

MaxSAT reasoning is an effective technology used in modern branch-and-bound (BnB) algorithms for the Maximum Weight Clique problem (MWC) to reduce the search space. However, the current MaxSAT reasoning approach for MWC is carried out in a blind manner and is not guided by any relevant strategy. In this paper, we describe a new BnB algorithm for MWC that incorporates a novel two-stage MaxSAT reasoning approach. In each stage, the MaxSAT reasoning is specialised and guided for different tasks. Experiments on an extensive set of graphs show that the new algorithm implementing this approach significantly outperforms relevant exact and heuristic MWC algorithms in both small/medium and massive real-world graphs.

## Introduction

In a vertex-weighted graph $G=(V, E, w)$, where $V$ is the set of vertices and $E$ is the set of edges, the weight function $w$ assigns a positive integer, called weight, to each vertex. A clique $C$ is a subset of $V$ in which every two vertices are adjacent in $G$. The size of a clique $C$ is its cardinality. The Maximum Clique Problem (MC) is to find a clique of maximum size in $G$. The weight of a clique $C$ is defined to be the total weight of vertices in $C$. The Maximum Weight Clique Problem (MWC), an important generalization of MC, is to find a clique of maximum weight in $G$, and its weight is denoted by $\omega_{v}(G)$.

MC and MWC are NP-hard problems (Garey and Johnson 1979) with applications in areas as diverse as coding theory (Zhian et al. 2013), protein structure prediction (Mascia et al. 2010), combinatorial auctions (Wu and Hao 2015b), computer vision (Zhang, Javed, and Shah 2014) and genomics (Butenko and Wilhelm 2006). Given their practical importance, considerable efforts have been devoted to develop both exact and heuristic algorithms for them.

There exist a remarkable number of algorithms for MC. We highlight the exact branch-and-bound ( BnB ) algorithms described in (Tomita et al. 2010; Li and Quan 2010; San et al. 2011; Jiang, Li, and Manyà 2016; Li, Jiang, and Manyà 2017), and the heuristic local search algorithms described in (Wu and Hao 2013; Benlic and Hao 2013; Pullan, Mascia,

[^0]and Brunato 2011). See (Wu and Hao 2015a) for a review on MC algorithms. Compared with the number of algorithms for MC, there are relatively fewer algorithms available for MWC. This is partially due to the fact that MWC is generally harder to solve than MC because of the different weight values of the vertices (Cai and Lin 2016; Jiang, Li, and Manyà 2017).

In this paper, we focus on algorithms for MWC. The most efficient heuristic algorithms for MWC are FastWClq (Cai and Lin 2016), MN/TS (Wu, Hao, and Glover 2012), LSCC+BMS (Wang, Cai, and Yin 2016), ReTS (Zhou, Hao, and Goëffon 2017) and RRWL (Fan et al. 2017). The most representative exact algorithms for MWC are Cliquer (Ostergard 2002), Kumlander's algorithm (Kumlander 2008), VCTable (Shimizu et al. 2012), OTClique (Shimizu et al. 2013), MWCLQ (Fang, Li, and Xu 2016) and WLMC (Jiang, Li, and Manyà 2017). Among them, we identify MWCLQ and WLMC as two of the most competitive algorithms. Both implement the BnB scheme and apply MaxSAT reasoning to improve the upper bound estimation. To our best knowledge, MWCLQ is specially good in small/medium dense graphs while WLMC exhibits the best performance in massive sparse graphs.

MaxSAT reasoning has been proven to be effective to reduce the search space in BnB algorithms for MWC. The current MaxSAT reasoning implemented in MWCLQ and WLMC relies on an upper bound $\left(\mathrm{UB}_{I S}\right)$ derived from the computation of an independent set (IS) partition of the vertices of the graph. However, as stated in (Jiang, Li, and Manyà 2017), $\mathrm{UB}_{I S}$ is very conservative. Moreover, the MaxSAT reasoning for improving $\mathrm{UB}_{I S}$ implemented in both MWCLQ and WLMC is carried out in a brute-force manner: It repeatedly and blindly applies unit IS propagation to detect disjoint subsets of conflicting ISs.

To overcome the conservativeness of $\mathrm{UB}_{I S}$ and improve the efficiency of MaxSAT reasoning on BnB algorithms, we propose a novel two-stage MaxSAT reasoning approach to reducing the search space. In each stage, MaxSAT reasoning is specialised and guided for different tasks. As a result, we develop a new MWC algorithm called TSM-MWC.

The conducted experiments on an extensive set of instances show that the two-stage MaxSAT reasoning approach is very effective on reducing the search space, and TSMMWC greatly outperforms relevant MWC algorithms in both small/medium and massive real-world graphs. To our best
knowledge, this is the first exact algorithm that reaches the best performance in both types of graphs.

The paper is organized as follows: Section 2 gives some basic graph definitions and reviews previous MaxSAT reasoning approaches for MWC. Section 3 presents the two-stage MaxSAT reasoning approach and the algorithm TSM-MWC. Section 4 reports on the empirical results. Section 5 gives the conclusions.

## Preliminaries

Let $G=(V, E, w)$ be a vertex-weighted undirected graph, where $V=\left\{v_{1}, \ldots, v_{n}\right\}$ is a set of $n$ vertices, $E$ is a set of $m$ edges, and $w$ is a weight function that assigns to each vertex $v_{i}$ of $V$ a non-negative integer $w\left(v_{i}\right)$ representing its weight. We also use $v_{i}^{w\left(v_{i}\right)}$ to represent that vertex $v_{i}$ has weight $w\left(v_{i}\right)$. The density of $G$ is $2 m /(n(n-1))$. Two vertices $v_{i}$ and $v_{j}$ of $V$ are adjacent, or neighbors, if $\left(v_{i}, v_{j}\right) \in E$. The set of neighbors of a vertex $v_{i}$ in $G$ is denoted by $\Gamma\left(v_{i}\right)=$ $\left\{v_{j} \mid\left(v_{i}, v_{j}\right) \in E\right\}$. The cardinality of $\Gamma\left(v_{i}\right)$ is the degree of $v_{i}$. The subgraph of $G$ induced by the subset $V^{\prime}$ of $V$, denoted by $G\left[V^{\prime}\right]$, is defined as $G\left[V^{\prime}\right]=\left(V^{\prime}, E^{\prime}, w\right)$, where $E^{\prime}=\left\{\left(v_{i}, v_{j}\right) \in E \mid v_{i}, v_{j} \in V^{\prime}\right\}$. The maximum weight in $V^{\prime}, \max _{v_{i} \in V^{\prime}}\left(w\left(v_{i}\right)\right)$, is denoted by $w^{*}\left(V^{\prime}\right)$, and $w^{*}(\emptyset)=$ 0 . A clique in $G=(V, E, w)$ is a subset $C$ of $V$ such that every two vertices in $C$ are adjacent. The weight of $C$ is $w(C)=\sum_{v_{i} \in C} w\left(v_{i}\right)$. An independent set (IS) of $G$ is a subset $D$ of $V$ in which no two vertices are adjacent. An IS partition of $G$ is a partition of the vertices of $V$ into ISs such that each vertex belongs to exactly one IS.

Let $S=\left\{v_{1}^{w\left(v_{1}\right)}, v_{2}^{w\left(v_{2}\right)}, \ldots, v_{r}^{w\left(v_{r}\right)}\right\}$ be a subset of vertices of $V$ with $w\left(v_{1}\right) \geq \cdots \geq w\left(v_{k}\right)>\beta \geq$ $w\left(v_{k+1}\right) \geq \cdots \geq w\left(v_{r}\right)$, where $\beta$ is an integer. The weight splitting operation $\operatorname{split}(S, \beta)$ returns the sets $S^{\prime}=\left\{v_{1}^{\beta}, v_{2}^{\beta}, \ldots, v_{k}^{\beta}, v_{k+1}^{w\left(v_{k+1}\right)}, \ldots, v_{r}^{w\left(v_{r}\right)}\right\}$ and $S^{\prime \prime}=$ $\left\{v_{1}^{w\left(v_{1}\right)-\beta}, v_{2}^{w\left(v_{2}\right)-\beta}, \ldots, v_{k}^{w\left(v_{k}\right)-\beta}\right\}$. In other words, for each vertex $v_{i} \in S$ with $w\left(v_{i}\right)>\beta, \operatorname{split}(S, \beta)$ splits the weight $w\left(v_{i}\right)$ into $\beta$ and $w\left(v_{i}\right)-\beta$.

## MaxSAT reasoning for MWC

To solve MWC with a BnB algorithm, it is crucial to compute a tight upper bound (UB) of $\omega_{v}(G)$ for a vertexweighted graph $G=(V, E, w)$. Given an IS partition $\Pi=\left\{D_{1}, D_{2}, \ldots, D_{r}\right\}$ of $G$, the UB of $\omega_{v}(G)$ based on ISs is defined to be $\mathrm{UB}_{I S}=\sum_{i=1}^{r} w^{*}\left(D_{i}\right)$, because a clique of $G$ contains at most one vertex from each IS. However, $\mathrm{UB}_{I S}$ is very conservative. It is tight only in the very special case where there is a maximum weight clique that contains the most weighted vertex of each IS in $\Pi$.

A subset of $k$ ISs that cannot form a clique of size $k$ is said conflicting (the $k$ ISs are also said conflicting). A special case is $k=2$ : two ISs $S_{1}$ and $S_{2}$ are conflicting iff $S_{1} \cup S_{2}$ is an IS. If $\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$ is a conflicting subset of ISs of $\Pi$ and $\beta=\min \left(w^{*}\left(S_{1}\right), w^{*}\left(S_{2}\right), \ldots, w^{*}\left(S_{k}\right)\right)$, then $\mathrm{UB}_{I S}-\beta$ is an improved UB of $\omega_{v}(G)$. This follows from the fact that, for every possible clique $C$, there is at least one IS $S$ in $\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$ such that $C \cap S=\emptyset$.

To increase the number of disjoint conflicting subsets of ISs, we split the ISs of the already detected conflicting subsets of ISs. Concretely, each $S_{i}(1 \leq i \leq k)$ of a conflicting subset $\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}$ of ISs can be split, using the operation $\operatorname{split}\left(S_{i}, \beta\right)$, into two ISs: $S_{i}^{\prime}$ and $S_{i}^{\prime \prime}$. Note that the subset $\Pi_{1}=\left\{S_{1}^{\prime}, S_{2}^{\prime}, \ldots, S_{k}^{\prime}\right\}$, where $w^{*}\left(S_{1}^{\prime}\right)=w^{*}\left(S_{2}^{\prime}\right)=$ $\cdots=w^{*}\left(S_{k}^{\prime}\right)=\beta$, is conflicting. Additional conflicting subsets of ISs, which are disjoint with $\left\{S_{1}^{\prime}, S_{2}^{\prime}, \ldots, S_{k}^{\prime}\right\}$, can be identified in $\left(\Pi \backslash\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}\right) \cup\left\{S_{1}^{\prime \prime}, S_{2}^{\prime \prime}, \ldots, S_{k}^{\prime \prime}\right\}$.

Since each conflicting subset of $k$ ISs implies the splitting of $k$ existing ISs, we finally obtain a set of ISs $\left\{D_{1}, D_{2}, \ldots, D_{q}\right\}$ that is the union $\Pi_{1} \cup \Pi_{2} \cup \ldots \cup \Pi_{p-1} \cup \Pi_{p}$, and each $\Pi_{i}, 1 \leq i \leq p-1$, is a conflicting subset of ISs. Since each vertex $v$ of $G$ belongs to at most one of the ISs of $\Pi_{i}$, we define a weight function $w_{i}(v)$ for each $\Pi_{i}$ as follows: $w_{i}(v)$ is 0 if $v$ does not belong to any IS of $\Pi_{i}$; otherwise $w_{i}(v)$ is the weight of $v$ in the IS of $\Pi_{i}$ in which $v$ appears. Obviously, each $v$ of $G$ can belong to several subsets of $\Pi_{1} \cup \Pi_{2} \cup \ldots \cup \Pi_{p-1} \cup \Pi_{p}$ and it must hold that $w(v)=\sum_{i=1}^{p} w_{i}(v)$.

Each $\Pi_{i}$ induces a graph $G_{i}$ that has the same set of vertices and the same set of edges as $G$, but with a different weight function $w_{i}(v)$. Let $C$ be a clique of $G$, then $w(C)=$ $\sum_{v \in C} w(v)=\sum_{v \in C} \sum_{i=1}^{p} w_{i}(v)=\sum_{i=1}^{p} \sum_{v \in C} w_{i}(v)$. Note that $C$ is also a clique in each $G_{i}$ and $G_{i}$ can be partitioned into a set of ISs $\left\{S_{1}^{\prime}, S_{2}^{\prime}, \ldots, S_{k_{i}}^{\prime}\right\}$. We have that $\sum_{v \in C} w_{i}(v) \leq \sum_{j=1}^{k_{i}} w_{i}^{*}\left(S_{j}^{\prime}\right)-\beta_{i}$ for $i<p$, because the ISs are conflicting. So, $w(C) \leq \sum_{i=1}^{p-1}\left(\sum_{j=1}^{k_{i}} w_{i}^{*}\left(S_{j}^{\prime}\right)-\right.$ $\left.\beta_{i}\right)+\sum_{j=1}^{k_{p}} w_{p}^{*}\left(S_{j}^{\prime}\right)=\sum_{i=1}^{p} \sum_{j=1}^{k_{i}} w_{i}^{*}\left(S_{j}^{\prime}\right)-\sum_{i=1}^{p-1} \beta_{i}=$ $\sum_{i=1}^{q} w_{i}^{*}\left(D_{i}\right)-\sum_{i=1}^{p-1} \beta_{i}$.

The improved upper bound $\mathrm{UB}_{\text {MaxSAT }}$, obtained by identifying and splitting conflicting ISs, is defined to be $\sum_{i=1}^{q} w_{i}^{*}\left(D_{i}\right)-\sum_{i=1}^{p-1} \beta_{i}$. It is implemented in the two best performing exact MWC algorithms, MWCLQ and WLMC.

Let $C^{*}$ be the clique of the greatest weight found so far in $G$. If $\mathrm{UB}_{\text {MaxSAT }}$ is not sufficient for pruning (i.e., $\mathrm{UB}_{\text {MaxSAT }}>w\left(C^{*}\right)$ ), further search is required to find a better clique in $G$. In this case, the effort spent to compute $\mathrm{UB}_{\text {MaxSAT }}$ in MWCLQ is lost. To overcome this drawback, the algorithm WLMC first identifies a subset $A$ of $V$ in such a way that $G[A]$ has an IS partition $\Pi$ and its $\mathrm{UB}_{I S}$ is not greater than $w\left(C^{*}\right)$. Let $B=V \backslash A=\left\{b_{1}, b_{2}, \ldots, b_{|B|}\right\}$. If $B=\emptyset$, the search is pruned, because $G$ does not contain any clique of weight greater than $w\left(C^{*}\right)$. Otherwise, WLMC successively adds $b_{i}$ as a unit IS $\left\{b_{i}\right\}$ to $\Pi$ for $i=|B|,|B|-1, \ldots, 1$. For each $b_{i}$, WLMC employs MaxSAT reasoning to compute $\mathrm{UB}_{M a x S A T}$ for $G\left[A \cup\left\{b_{i}\right\}\right]$. If the computed $\mathrm{UB}_{\operatorname{MaxSA} A T}$ is not greater than $w\left(C^{*}\right), b_{i}$ is removed from $B$ and added to $A$, because a clique of weight greater than $w\left(C^{*}\right)$ cannot be found in $G\left[A \cup\left\{b_{i}\right\}\right]$. In this way, the number of vertices of $B$ is greatly reduced by MaxSAT reasoning. Finally, WLMC only needs to branch on the vertices remaining in $B$ to find a clique better than $C^{*}$.

Note that the computation of $\mathrm{UB}_{\text {MaxSAT }}$ in MWCLQ and WLMC is based on $\mathrm{UB}_{I S}$, which is very conservative. Moreover, MWCLQ and WLMC identify a conflicting subset of ISs by repeatedly and blindly applying unit clause propaga-
tion or unit IS propagation, which is a brute force approach and might impede the computation of a tighter UB.

## TSM-MWC: A BnB MWC Algorithm with Two-stage MaxSAT Reasoning

In this section, we describe the new BnB MWC algorithm TSM-MWC. We first present the basic BnB search procedure that TSM-MWC implements, and then describe a novel two-stage MaxSAT reasoning procedure (TSM) to reduce the number of branching vertices of the search procedure. Finally, we define TSM-MWC, which combines an efficient preprocessing and the novel two-stage MaxSAT reasoning.

## The basic BnB search procedure

Algorithm 1 presents the basic BnB search procedure that TSM-MWC implements. Given a graph $G=(V, E, w)$, a vertex ordering $O$ over $V$, a growing clique $C$, a candidate set of vertices $P$ in which every vertex is adjacent to every vertex in $C$, and the clique $C^{*}$ of the greatest weight found so far in $G$, the algorithm calls the GetBranches function to partition $P$ into $A$ and $B$ in such a way that $\omega_{v}(G[A]) \leq$ $w\left(C^{*}\right)-w(C)$ and $B=V \backslash A=\left\{b_{1}, b_{2}, \ldots, b_{|B|}\right\}$ is the returned set of branching vertices. If $B$ is empty, the current search is pruned, because the clique $C$ cannot be grown to a clique of weight greater than $w\left(C^{*}\right)$ with the vertices of $P$. Otherwise, the algorithm recursively branches on $b_{i}$, for $i=|B|,|B|-1, \ldots, 1$, to search for a clique containing $b_{i}$ of weight greater than $w\left(C^{*}\right)$ in $G\left[\Gamma\left(b_{i}\right) \cap\right.$ $\left.\left(\left\{b_{i+1}, \ldots, b_{|B|}\right\} \cup A\right)\right]$. If the initial call to the algorithm is SearchMWC $(G, V, O, \emptyset, \emptyset)$, it returns a maximum weight clique of $G$ after exploring the whole search space.

The crucial component of Algorithm 1 is the GetBranches function. The smaller the cardinality of the set of branching vertices $B$ returned by GetBranches, the lower the number of branches that need to be explored to find an optimal solution. So, in the sequel, we will focus on developing a better GetBranches function based on MaxSAT reasoning.

## Two-stage MaxSAT Reasoning to Minimize the Number of Branches

We describe a two-stage MaxSAT reasoning approach that considers in priority conflicting subsets containing two or three ISs, allowing to reduce more branches than previous MaxSAT reasoning approaches.
Stage 1. Given a vertex-weighted graph $G=(V, E, w)$, a lower bound $t$ of $\omega_{v}(G)$ and a vertex ordering $O: v_{1}<$ $v_{2}<\cdots<v_{n}$, Algorithm 2 defines a simplified MaxSAT reasoning approach to computing an initial set of branching vertices $B$ and a set $\Pi$ of ISs of $V \backslash B$ so that $\omega_{v}(G[V \backslash B]) \leq$ $\sum_{D \in \Pi} w^{*}(D) \leq t$. Thus, to search for a clique of weight greater than $t$, it suffices to branch on the vertices of $B$.

Initially, $B$ and $\Pi$ are empty. For $i=n$ to 1 , if every IS of $\Pi$ contains at least one neighbor of $v_{i}$, Algorithm 2 adds the new IS $\left\{v_{i}\right\}$ to $\Pi$ if $\sum_{D \in \Pi} w^{*}(D)+w\left(v_{i}\right) \leq t$ (lines 10-11). Otherwise, the algorithm splits the weight $w\left(v_{i}\right)$ among some ISs $S_{1}, S_{2}, \ldots, S_{k}$ of $\Pi$ not containing any neighbor of $v_{i}$ by applying the following lemma.

Lemma 1. Let $G=(V, E, w)$ be a vertex-weighted graph, let $\Pi=\left\{D_{1}, D_{2}, \ldots, D_{r}\right\}$ be a set of ISs, let $V(\Pi)$ be the set of vertices occurring in $\Pi$, let $v_{i}$ be a vertex of $V \backslash V(\Pi)$, and let $S_{1}, S_{2}, \ldots, S_{k}$ be ISs of $\Pi$ not containing any neighbor of $v_{i}$ (i.e., conflicting with $\left\{v_{i}\right\}$ ). Then, $\sum_{D \in \Pi} w^{*}(D)+\max \left(w\left(v_{i}\right)-\sum_{j=1}^{k} w^{*}\left(S_{j}\right), 0\right)$ is an upper bound of $\omega_{v}\left(G\left[V(\Pi) \cup\left\{v_{i}\right\}\right]\right)$.

Proof. Let $C$ be a maximum weight clique in $G\left(V(\Pi) \cup\left\{v_{i}\right\}\right)$. If $v_{i} \in C$, then $C$ cannot contain any vertex from $S_{1}, S_{2}$, $\ldots, S_{k}$ and $\sum_{D \in \Pi \backslash\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}} w^{*}(D)+w\left(v_{i}\right)=$ $\sum_{D \in \Pi} w^{*}(D)+w\left(v_{i}\right)-\sum_{j=1}^{k} w^{*}\left(S_{j}\right)$ is an upper bound of $\omega_{v}\left(G\left[V(\Pi) \cup\left\{v_{i}\right\}\right]\right)$. If $v_{i} \notin C, \sum_{D \in \Pi} w^{*}(D)$ is an upper bound of $\omega_{v}\left(G\left[V(\Pi) \cup\left\{v_{i}\right\}\right]\right)$. Hence, $\sum_{D \in \Pi} w^{*}(D)+\max \left(w\left(v_{i}\right)-\sum_{j=1}^{k} w^{*}\left(S_{j}\right), 0\right)$ is an upper bound of $\omega_{v}\left(G\left[V(\Pi) \cup\left\{v_{i}\right\}\right]\right)$ in both cases.

Let $u b=\sum_{D \in \Pi} w^{*}(D)$ and let $\delta=w\left(v_{i}\right)$. If $u b+$ $\max \left(\delta-w^{*}\left(S_{1}\right), 0\right) \leq t$, then Algorithm 2 inserts $v_{i}^{\delta}$ into $S_{1}$ and updates $u b$ to $u b+\max \left(\delta-w^{*}\left(S_{1}\right), 0\right)$, because $G\left[V(\Pi) \cup\left\{v_{i}\right\}\right]$ cannot contain any clique of weight greater than $t$ in this case according to Lemma 1. Otherwise, Algorithm 2 inserts $v_{i}^{w^{*}\left(S_{1}\right)}$ into $S_{1}$ in order not to increase $w^{*}\left(S_{1}\right)$, updates $\delta$ to $\delta-w^{*}\left(S_{1}\right)$, and tries to insert $v_{i}^{\delta}$ into $S_{2}$, and so on (lines 16-23). In a word, Algorithm 2 splits $v_{i}^{w\left(v_{i}\right)}$ into $v_{i}^{w^{*}\left(S_{1}\right)}, v_{i}^{w^{*}\left(S_{2}\right)}, \ldots, v_{i}^{w^{*}\left(S_{k^{\prime}-1}\right)}, v_{i}^{\delta}$, where $\delta=$ $w\left(v_{i}\right)-\sum_{j=1}^{k^{\prime}-1} w^{*}\left(S_{j}\right)$ and $k^{\prime}$ is the smallest integer such that $k^{\prime} \leq k$ and $u b+\max \left(w\left(v_{i}\right)-\sum_{j=1}^{k^{\prime}} w^{*}\left(S_{j}\right), 0\right) \leq t$. It adds $v_{i}^{w^{*}\left(S_{j}\right)}$ to $S_{j}$ for $j=1$ to $k^{\prime}-1$, inserts $v_{i}^{\delta}$ into $S_{k^{\prime}}$, and updates $u b$ to $u b+\max \left(w\left(v_{i}\right)-\sum_{j=1}^{k^{\prime}} w^{*}\left(S_{j}\right), 0\right)$. If such a $k^{\prime}$ does not exist, the algorithm inserts $v_{i}$ into $B$ and restores $\Pi$ to the values it had before considering $v_{i}$ (line 24). Finally, it returns the set $B$, the set $\Pi$ of ISs on $V \backslash B$ and an upper bound $u b$ of $\omega_{v}(G[V \backslash B])$.

                        restore all removed vertices into their ISs;
                for \(j:=1\) to \(k\) do
                if \(u b+\max \left(\delta-w^{*}\left(S_{j}\right), 0\right) \leq t\) then
                \(S_{j} \leftarrow S_{j} \cup\left\{v_{i}^{\delta}\right\} ;\)
                                \(u b \leftarrow u b+\max \left(\delta-w^{*}\left(S_{j}\right), 0\right) ;\)
                                \(\delta \leftarrow 0\); break;
                    else
                    \(S_{j} \leftarrow S_{j} \cup\left\{v_{i}^{w^{*}\left(S_{j}\right)}\right\} ;\)
                    \(\delta \leftarrow \delta-w^{*}\left(S_{j}\right) ;\)
                if \(\delta>0\) then \(\Pi \leftarrow \Pi^{\prime}, B \leftarrow B \cup\left\{v_{i}\right\} ;\)
        return \((B, \Pi, u b)\);
The key of Algorithm 2 is the identification of the ISs \(S_{1}, \ldots, S_{k}\), which are conflicting with \(\left\{v_{i}\right\}\), and the splitting of \(w\left(v_{i}\right)\) among these ISs, which is referred to as binary MaxSAT reasoning, because \(\left\{S_{j},\left\{v_{i}\right\}\right\}(1 \leq j \leq k)\) is a binary conflicting subset of ISs. Note that \(\Pi\) is not an IS partition of \(G[V \backslash B]\) in the strict sense, because a vertex can belong to several ISs of \(\Pi\).
Let \(\theta\) be the greatest weight among the vertices of \(V\). Each vertex \(v \in V\) has at most \(w(v)\) occurrences in \(\Pi\). So, the total number of vertices in \(\Pi\) is in \(O(\theta \times|V|)\). The main cost of inserting a vertex \(v\) into \(\Pi\) is the identification of the ISs

                \(B \leftarrow B \backslash\left\{b_{i}\right\}, u b \leftarrow u b+\delta ;\)
            else \(\Pi \leftarrow \Pi^{\prime}\);
            else \(\Pi \leftarrow \Pi^{\prime}\);
        return \(B\);
```

```
        return \(B\);
```

```

Concretely, let \(B=\left\{b_{1}, b_{2}, \ldots, b_{|B|}\right\}\) with \(b_{1}<b_{2}<\) \(\cdots<b_{|B|}\) w.r.t. the ordering \(O\) and let \(u b=\sum_{D \in \Pi} w^{*}(D)\). For each \(b_{i}(1 \leq i \leq|B|)\), note that \(u b+w\left(b_{i}\right)\) is an upper bound of \(\omega_{v}\left(G\left[V(\Pi) \cup\left\{b_{i}\right\}\right]\right)\). Algorithm 3 improves this upper bound by first identifying a set of ISs \(\left\{S_{1}, S_{2}, \ldots, S_{k}\right\}\) in \(\Pi\) not containing any neighbor of \(b_{i}\), splitting \(w\left(b_{i}\right)\) into \(w^{*}\left(S_{1}\right), w^{*}\left(S_{2}\right), \ldots, w^{*}\left(S_{k}\right)\), and \(\delta\), where \(\delta=w\left(b_{i}\right)-\) \(\sum_{j=1}^{k} w^{*}\left(S_{j}\right)\), and inserting \(b_{i}^{w^{*}\left(S_{j}\right)}\) into \(S_{j}(1 \leq j \leq k)\) (lines 6 and 7). After these insertions, the upper bound of \(\omega_{v}\left(G\left[V(\Pi) \cup\left\{b_{i}\right\}\right]\right)\) is improved to \(u b+\delta\). Note that \(\delta>0\) because \(b_{i}\) was not entirely inserted into \(\Pi\) in Stage 1. \(S_{1}, S_{2}, \ldots, S_{k}\) not containing any neighbor of \(v\). So, the time complexity of inserting a vertex into \(\Pi\) is in \(O(\theta \times|V|)\), and the time complexity of Algorithm 2 is in \(O\left(\theta \times|V|^{2}\right)\).

Stage 2. This stage is implemented in Algorithm 3. Its aim is to further reduce the set \(B\) of branching vertices returned by Algorithm 2 together with the set of ISs \(\Pi\) on \(V \backslash B\). To remove a vertex \(b\) from \(B\), the algorithm checks if \(\omega_{v}(G[V(\Pi) \cup\{b\}]) \leq t\) to prove that branching on \(b\) is not necessary. For this purpose, it identifies conflicting subsets of ISs in \(\Pi \cup\{\{b\}\}\) in an ordered way: Firstly, the conflicting subsets containing 2 ISs are identified; secondly, the conflicting subsets containing 3 ISs; and finally, the conflicting subsets containing more than 3 ISs. We refer to this MaxSAT reasoning approach as ordered MaxSAT reasoning.

Then, Algorithm 3 identifies a set of ISs \(\left\{U_{1}, U_{2}, \ldots, U_{r}\right\}\) containing exactly one neighbor of \(b_{i}\). For each \(U_{j}(1 \leq\) \(j \leq r\) ), let \(u\) be the unique neighbor of \(b_{i}\) in \(U_{j}\). The algorithm tries to identify an IS \(D_{q}\) such that \(D_{q} \cap \Gamma\left(b_{i}\right) \cap\) \(\Gamma(u)=\emptyset\). Thus, \(\left\{\left\{b_{i}^{\delta}\right\}, U_{j}, D_{q}\right\}\) is conflicting. Let \(\beta=\) \(\min \left(\delta, w^{*}\left(U_{j}\right), w^{*}\left(D_{q}\right)\right)\), the algorithm splits \(b_{i}^{\delta}\) into \(b_{i}^{\beta}\) and \(b_{i}^{\delta-\beta}\), and \(U_{j}\left(D_{q}\right)\) into \(U_{j}^{\prime}\left(D_{q}^{\prime}\right)\) and \(U_{j}^{\prime \prime}\left(D_{q}^{\prime \prime}\right)\) using the operation \(\operatorname{split}\left(U_{j}, \beta\right)\left(\operatorname{split}\left(D_{q}, \beta\right)\right)\) defined in Section Preliminaries. Note that the maximum weight in both \(U_{j}^{\prime}\) and \(D_{q}^{\prime}\) is \(\beta\), and the upper bound of \(\omega_{v}\left(G\left[V(\Pi) \cup\left\{b_{i}\right\}\right]\right)\) is improved to \(u b+\delta-\beta\) with the conflicting subset \(\left\{\left\{b_{i}^{\beta}\right\}, U_{j}^{\prime}, D_{q}^{\prime}\right\}\). Note that \(U_{j}^{\prime}\) and \(D_{q}^{\prime}\) cannot be used for other improvements and are excluded from \(\Pi\) together with \(U_{j}\) and \(D_{q}\) (line 15). After the improvement, \(\delta\) is updated to \(\delta-\beta\) (line 16).

After working on all ISs in \(\left\{U_{1}, U_{2}, \ldots, U_{r}\right\}\), if \(u b+\delta\) is still greater than \(t\), Algorithm 3 repeatedly detects disjoints conflicting subsets of ISs to improve \(u b+\delta\); similarly to the approach implemented in MWCLQ and WLMC. For each detected disjoint conflicting subset of ISs \(\left\{S_{0}, S_{1}, \ldots, S_{p}\right\}\), let \(\beta=\min \left(w^{*}\left(S_{0}\right), w^{*}\left(S_{1}\right), \ldots, w^{*}\left(S_{p}\right)\right)\). The algorithm splits every \(S_{j}(0 \leq j \leq p)\) into \(S_{j}^{\prime}\) and \(S_{j}^{\prime \prime}\) with the operation \(\operatorname{split}\left(S_{j}, \beta\right)\) and improves \(u b+\delta\) by \(\beta\) (lines 26-30). Finally, if the improved UB of \(\omega_{v}\left(G\left[V(\Pi) \cup\left\{b_{i}\right\}\right]\right)\) is not greater than \(t, b_{i}\) is removed from \(B\), because branching on \(b_{i}\) is not necessary for finding a clique of weight greater than \(t\). Otherwise, the algorithm restores \(\Pi\) to the values it had before considering \(b_{i}\).

The time complexity of Algorithm 3 is dominated by the third part (line 18-31) of the detection of the conflicting subsets containing more than 3 ISs. So, its time complexity is similar to the MaxSAT reasoning approach in WLMC.

The next example illustrates the benefits of the two-stage MaxSAT reasoning approach in reducing the number of branches, and compares it with the standard IS partition approach and the brute-force MaxSAT reasoning in WLMC.

Figure 1: Two graphs for Example 1
Example 1. Let \(G=(V, E, w)\) be the left graph (a) of Figure 1, where \(v_{i}^{w_{i}}\) denotes that the weight of vertex \(v_{i}\) is \(w_{i}\), let \(O: v_{6}<v_{5}<\cdots<v_{1}\) be the vertex ordering and let \(t=6\). Using the standard IS partition approach, the vertices \(v_{1}, \ldots, v_{5}\) can be sequentially inserted into three ISs: \(D_{1}=\left\{v_{1}^{3}, v_{3}^{2}\right\}, D_{2}=\left\{v_{2}^{2}, v_{4}^{2}\right\}\) and \(D_{3}=\left\{v_{5}^{1}\right\}\) with \(\mathrm{UB}_{I S}=3+2+1=6 \leq t\). Nevertheless, the last vertex \(v_{6}^{4}\) cannot be inserted into \(D_{1}\) or \(D_{2}\), because then \(\mathrm{UB}_{I S}\) would be at least 7 , which is greater than \(t\). So, \(B=\left\{v_{6}^{4}\right\}\) is the set of branching vertices computed with the standard

IS partition approach. However, with the binary MaxSAT reasoning in Stage 1 (Algorithm 2), \(D_{1}\) and \(D_{2}\) are identified, and the algorithm inserts \(v_{6}^{3}\) into \(D_{1}\) and \(v_{6}^{1}\) into \(D_{2}\) so that the computed \(\mathrm{UB}=6+\max \{4-(3+2), 0\}=6\) is not yet greater than \(t\). As a result, the returned set \(B\) of branching vertices for the left graph \((a)\) of Figure 1 is the empty set.

We illustrate the benefits of the ordered MaxSAT reasoning in Stage 2 with the right graph \((b)\) of Figure 1. Let \(v_{9}<v_{8}<\cdots<v_{1}\) be the vertex ordering \(O\) and let \(t=8\). Using the standard IS partition approach, \(v_{1}, \ldots, v_{7}\) can be partitioned into three ISs: \(D_{1}=\left\{v_{1}^{2}, v_{2}^{4}, v_{4}^{1}\right\}, D_{2}=\left\{v_{3}^{2}, v_{5}^{2}\right\}\) and \(D_{3}=\left\{v_{6}^{2}, v_{7}^{1}\right\}\) with \(\mathrm{UB}_{I S}=4+2+2=8 \leq t\). Nevertheless, \(v_{8}^{2}\) and \(v_{9}^{2}\) cannot be inserted into any of the three ISs. Hence, the initial set of branching vertices is \(B=\left\{v_{8}^{2}, v_{9}^{2}\right\}\). To reduce \(B\), we apply MaxSAT reasoning. First, we add \(\left\{v_{8}^{2}\right\}\) to the set of ISs as a unit IS, and \(\mathrm{UB}_{I S}=10\). The propagation of the unit IS \(\left\{v_{8}^{2}\right\}\) removes \(v_{1}^{2}, v_{5}^{2}\) and \(v_{7}^{1}\) from their ISs, resulting in two new unit ISs: \(D_{2}=\left\{v_{3}^{2}\right\}\) and \(D_{3}=\left\{v_{6}^{2}\right\}\). With brute-force MaxSAT reasoning, we select \(D_{2}=\left\{v_{3}^{2}\right\}\) and propagate it, removing \(v_{4}^{1}\) from \(D_{1}\). We then propagate \(D_{3}=\left\{v_{6}^{2}\right\}\), removing \(v_{2}^{4}\) from \(D_{1}\) and making \(D_{1}\) empty. Since \(\left\{v_{8}^{2}\right\}, D_{2}\) and \(D_{3}\) are the reasons for removing \(v_{1}^{2}, v_{4}^{1}\) and \(v_{2}^{4}\) from \(D_{1}\), respectively, \(\left\{D_{1}, D_{2}, D_{3},\left\{v_{8}^{2}\right\}\right\}\) is a conflicting subset of ISs and \(\mathrm{UB}_{I S}\) can be improved to \(\mathrm{UB}_{I S}-\beta=10-2=8 \leq t\), where \(\beta=\min \left\{w^{*}\left(D_{1}\right), w^{*}\left(D_{2}\right), w^{*}\left(D_{3}\right), w^{*}\left(\left\{v_{8}^{2}\right\}\right)\right\}=2\).
After splitting \(D_{1}, D_{2}, D_{3}\) and \(\left\{v_{8}^{2}\right\}\) with the operation \(\operatorname{split}(D, \beta)\), the ISs \(D_{2}, D_{3}\) and \(\left\{v_{8}^{2}\right\}\) are removed from the partition, because their maximum vertex weight is equal to \(\beta\), and \(D_{1}\) is split into \(D_{1}^{\prime}=\left\{v_{1}^{2}, v_{2}^{2}, v_{4}^{1}\right\}\) and \(D_{1}^{\prime \prime}=\left\{v_{2}^{2}\right\}\) ( \(D_{1}^{\prime}\) is removed from the partition). After that, we cannot identify any new conflict subset when we add \(\left\{v_{9}^{2}\right\}\) to the set of ISs, because \(v_{9}^{2}\) is adjacent to \(v_{2}^{2}\) in \(D_{1}^{\prime \prime}\). Finally, the returned branching set is \(B=\left\{v_{9}^{2}\right\}\).

However, if we use the ordered MaxSAT reasoning in Stage 2 (Algorithm 3), we can remove \(v_{9}^{2}\) from \(B\). Indeed, after propagating the new unit IS \(\left\{v_{8}^{2}\right\}\), we have two new unit ISs: \(D_{2}=\left\{v_{3}^{2}\right\}\) and \(D_{3}=\left\{v_{6}^{2}\right\}\). According to Algorithm 3, the conflicting subsets containing two or three ISs are detected in priority. Hence, the algorithm identifies the conflicting subset \(\left\{D_{1}, D_{3},\left\{v_{8}^{2}\right\}\right\}\), because the neighbors of \(v_{8}^{2}\) in \(D_{1}\) and \(D_{3}\) are not adjacent, and \(\mathrm{UB}_{I S}\) is improved to \(\mathrm{UB}_{I S}-\beta=8 \leq t\), where \(\beta=\min \left\{w^{*}\left(D_{1}\right), w^{*}\left(D_{3}\right), w^{*}\left(\left\{v_{8}^{2}\right\}\right)\right\}=2\). After splitting \(D_{1}, D_{3}\) and \(\left\{v_{8}^{2}\right\}\) with the operation \(\operatorname{split}(D, \beta)\), the remaining ISs are \(D_{1}^{\prime \prime}=\left\{v_{2}^{2}\right\}\) and \(D_{2}=\left\{v_{3}^{2}, v_{5}^{2}\right\}\). We then add \(\left\{v_{9}^{2}\right\}\) to the set of ISs, increasing \(\mathrm{UB}_{I S}\) to 10 . Now, we can easily detect a new conflicting subset of ISs: \(\left\{D_{1}^{\prime \prime}, D_{2},\left\{v_{9}^{2}\right\}\right\}\), because \(D_{2}\) does not contain any vertex that is adjacent to both \(v_{2}^{2}\) and \(v_{9}^{2}\), and \(\mathrm{UB}_{I S}\) is improved to \(\mathrm{UB}_{I S}-2=8 \leq t\). So, \(v_{9}^{2}\) is removed from \(B\). Finally, the returned branching set for the right graph (b) of Figure 1 is the empty set.

Note that, in Stage 1, binary MaxSAT reasoning does not remove any IS from the set \(\Pi\) of ISs. So, ordered MaxSAT reasoning can consider all the ISs in \(\Pi\) in Stage 2. This is beneficial for detecting more disjoint conflicting subsets of ISs to reduce the number of branches. That is the rationale behind carrying out MaxSAT reasoning in two stages.

Combining Algorithm 2 and Algorithm 3, we can easily implement the GetBranches function in Algorithm 4 to minimize the number of branching vertices.
```

Algorithm 4: GetBranches $(G, t, O)$
Input: $G=(V, E, w)$, an integer $t$ and an ordering $O$
Output: a set $B$ of branching vertices
begin
$(B, \Pi, u b) \leftarrow$ BinaryMaxSAT $(G, t, O) ;$
if $B$ is not empty then
$B \leftarrow$ OrderedMaxSAT $(G, t, O, B, \Pi, u b) ;$
return $B$;

```

\section*{Algorithm TSM-MWC}

Preprocessing is crucial for the efficiency of BnB algorithms for MWC, especially on massive real-world graphs. Thus, to obtain the new exact algorithm TSM-MWC (Algorithm 5), we combine the efficient preprocessing of Algorithm WLMC with Algorithm 1.

Given \(G=(V, E, w)\) and a lower bound \(t\) of \(\omega_{v}(G)\), the preprocessing procedure Initialize \((G, t)\) of WLMC performs three tasks: it derives a vertex ordering \(O\), seeks an initial clique \(C_{0}\) and reduces the input graph \(G\) to a simpler graph \(G^{\prime}\). Initialize \((G, t)\) computes the vertex ordering \(O: v_{1}<v_{2}<\cdots<v_{n}\) as follows: Given a copy \(H\) of \(G\), it removes the vertex with the smallest degree in \(H\) and names it \(v_{1}\); then, it removes the vertex with the smallest degree in \(H\left[V \backslash\left\{v_{1}\right\}\right]\) and names it \(v_{2}\), and so on. After removing the vertices \(v_{1}, v_{2}, \ldots, v_{i}\) from \(H\), if the smallest degree in \(H\left[V \backslash\left\{v_{1}, v_{2}, \ldots, v_{i}\right\}\right]\) is \(|V|-i-1\), then \(V \backslash\left\{v_{1}, v_{2}, \ldots, v_{i}\right\}\) becomes the initial clique \(C_{0}\). If \(w\left(C_{0}\right)>t, t=w\left(C_{0}\right)\). Initialize \((G, t)\) returns \(\left(C_{0}, O, G\left[V^{\prime}\right]\right)\), where \(V^{\prime}=\{v \mid\) \(w(\{v\} \cup \Gamma(v))>t\}\).

TSM-MWC calls Initialize \((G, t)\) to preprocess the original graph \(G\) (line 2) and all the first level subgraphs \(G[P]\) (line 8), and then calls SearchMWC (Algorithm 1) to search for a clique of weight greater than \(w\left(C^{*}\right)\) in the reduced subgraph \(G^{\prime \prime}\) (line 12).

\section*{Empirical Investigation}

We empirically evaluated TSM-MWC and compared it with two of the most competitive and recent exact algorithms (also called solvers), MWCLQ (Fang, Li, and Xu 2016) and WLMC (Jiang, Li, and Manyà 2017), and FastWClq (Cai and Lin 2016), one of the best heuristic MWC solvers.

TSM-MWC was implemented in C and compiled using GNU gcc -O3. Its source code is available at http://home.mis.u-picardie.fr/~cli/EnglishPage.html. MWCLQ, WLMC and FastWClq were compiled using their Makefiles. Experiments were performed on Intel Xeon CPUs E5-2680 v4@2.40GHz under Linux with 128GB of memory. We considered three datasets:
- DIMACS graphs: 80 graphs containing up to 4000 vertices with densities ranging from 0.03 to 0.99 . \({ }^{1}\)

\footnotetext{
\({ }^{1}\) available at http://cs.hbg.psu.edu/txn131/clique.html
}
```

Algorithm 5: TSM-MWC $(G)$, an exact algorithm for
MWC
Input: $G=(V, E, w)$
Output: a maximum weight clique $C^{*}$ of $G$
begin
$\left(C_{0}, O_{0}, G^{\prime}\right) \leftarrow \operatorname{Initialize}(G, 0)$;
$C^{*} \leftarrow C_{0}, V^{\prime} \leftarrow$ the vertex set of $G^{\prime}$;
order $V^{\prime}$ w.r.t. the initial ordering $O_{0}$;
for $i:=\left|V^{\prime}\right|$ downto 1 do
$C \leftarrow\left\{v_{i}\right\}, P \leftarrow$
$\Gamma\left(v_{i}\right) \cap\left\{v_{i+1}, v_{i+2}, \ldots, v_{\left|V^{\prime}\right|}\right\}$;
if $w(P)+w(C)>w\left(C^{*}\right)$ then
$\left(C_{0}^{\prime}, O_{0}^{\prime}, G^{\prime \prime}\right)$
$\leftarrow$ Initialize $\left(G[P], w\left(C^{*}\right)-w(C)\right)$;
if $w\left(C_{0}^{\prime}\right)+w(C)>w\left(C^{*}\right)$ then
$C^{*} \leftarrow C_{0}^{\prime} \cup C ;$
$V^{\prime \prime} \leftarrow$ the vertex set of $G^{\prime \prime}$;
$C_{1} \leftarrow$
Search $M W C\left(G^{\prime \prime}, V^{\prime \prime}, O_{0}^{\prime}, C, C^{*}\right)$;
if $w\left(C_{1}\right)>w\left(C^{*}\right)$ then $C^{*} \leftarrow C_{1}$;
return $C^{*}$;

```
- Real-world massive graphs: 215 real-world sparse graphs from the Network Data Repository, containing up to 66 M vertices and 1800 M edges. \({ }^{2}\)
- Graphs from MWC practical applications: There are four groups: The winner determination problem (WDP), error-correcting codes (ECC), kidney-exchange schemes (KES) and the research excellence framework (REF). They contain up to 8900 vertices with densities ranging from 0.04 to 0.98 , and were recently recommended in (McCreesh et al. 2017) to evaluate MWC algorithms. \({ }^{3}\)
The weights in the first two datasets are assigned as in the most relevant literature. The weights in the third dataset represent real meanings and can be very large; e.g. the vertex weight represents the price of a bid in the WDP graphs, and the paper ranking in the REF graphs.

We first compare TSM-MWC with MWCLQ, WLMC and FastWClq, and then analyze the effect of the two-stage MaxSAT reasoning in TSM-MWC. To compare the heuristic solver FastWClq with the exact solvers, FastWClq solved each graph 10 times with different seeds. The mean time to reach the best solution in each run (avgt), and the best solution found over the 10 runs are reported (best).

\section*{Comparison of TSM-MWC with Other Solvers}

We solved 80 DIMACS graphs using a cutoff time of 5000s to evaluate TSM-MWC on small/medium dense graphs. The exact solvers TSM-MWC, MWCLQ and WLMC solved 66, 61 and 60 DIMACS graphs, respectively. Table 1 shows the results for the 34 instances resulting of excluding the easy graphs that all the exact solvers solved within 1s, and the hard

graphs that were not solved by any exact solvers within 5000s. Among the 34 instances, FastWClq did not find the optimal solution of three instances (marked with ' \(\downarrow\) '). In general, TSM-MWC greatly outperforms the compared solvers on the DIMACS graphs.

To evaluate TSM-MWC on massive graphs, we solved 215 real-world graphs from the Network Data Repository (Rossi and Ahmed 2015), including the 52 graphs used to evaluate WLMC in (Jiang, Li, and Manyà 2017), the 90 graphs used to evaluate FastWClq in (Cai and Lin 2016), and 25 hard graphs of brain networks. MWCLQ is not compared because it was not designed for massive graphs. The cutoff time was set to 1000 s except for 3 biological graphs and the 25 graphs of brain networks, which used a cutoff time of 10000s. All the times, in seconds, include the preprocessing and search times, but not the time to read the input graphs.

Table 2 excludes the 168 graphs that were solved by both TSM-MWC and WLMC within 10s, and shows results for the

\end{tabular}
and FastWClq on the tested real-world massive graphs.
Table 3 compares the number of instances solved (i.e. an optimal solution was found) within a cutoff time of 3600 s and the mean runtimes of TSM-MWC, MWCLQ, WLMC and FastWClq in the four groups of graphs coming from practical applications of MWC. TSM-MWC solves the most number of instances in every group, and is generally faster than the other solvers. For example, TSM-MWC solves 13, 2 and 12 KES graphs more than MWCLQ, WLMC and FastWClq, and is almost 2, 3 and 9 times faster than MWCLQ, WLMC and FastWClq on WDP graphs, respectively. Overall, TSMMWC shows the best performance on the graphs coming from practical applications of MWC.

Table 4 compares the number of instances solved by TSMMWC, MWCLQ and WLMC within the cutoff time of each group of instances, as well as the mean search tree size of the solved instances in each group. TSM-MWC solves the greatest number of instances in each group and its search trees are also the smallest, showing that the new two-stage MaxSAT reasoning approach implemented in TSM-MWC is more effective than the brute-force MaxSAT reasoning of MWCLQ and WLMC in reducing the search space. Note that the mean search tree size of TSM-MWC for the DIMACS graphs is greater than that of WLMC, because TSM-MWC solves six hard DIMACS graphs more than WLMC within the cutoff time and the mean search tree size is computed among the solved graphs.

Table 4: The number of solved graphs (\#) and mean search tree size in \(10^{5}\) (tree) of TSM-MWC, MWCLQ and WLMC.
\begin{tabular}{l|cc|cr|cr}

\cline { 2 - 9 } & \(\#\) & tree & \(\#\) & tree & \(\#\) & tree & \(\#\) & tree \\
\hline DIMACS (80) & 54 & 305 & \(\mathbf{6 4}\) & \(\mathbf{1 9 8}\) & 60 & 24.1 & \(\mathbf{6 6}\) & 164 \\
MASSIVE(47) & 15 & 7.51 & \(\mathbf{3 4}\) & 30.4 & 30 & 11.5 & \(\mathbf{3 5}\) & 13.1 \\
WDP (499) & \(\mathbf{4 9 9}\) & 74.2 & \(\mathbf{4 9 9}\) & \(\mathbf{6 . 0 5}\) & \(\mathbf{4 9 9}\) & 8.69 & \(\mathbf{4 9 9}\) & \(\mathbf{4 . 3 6}\) \\
ECC (15) & \(\mathbf{1 5}\) & 66.0 & \(\mathbf{1 5}\) & \(\mathbf{2 5 . 0}\) & \(\mathbf{1 5}\) & 33.4 & \(\mathbf{1 5}\) & \(\mathbf{2 6 . 1}\) \\
KES (100) & 80 & 43.3 & \(\mathbf{8 2}\) & \(\mathbf{2 1 . 4}\) & 80 & 33.0 & \(\mathbf{8 1}\) & \(\mathbf{3 0 . 2}\) \\
REF (129) & \(\mathbf{1 0 6}\) & 10.7 & \(\mathbf{1 0 6}\) & \(\mathbf{5 . 8 9}\) & \(\mathbf{1 0 6}\) & 8.88 & \(\mathbf{1 0 6}\) & \(\mathbf{8 . 4 8}\) \\
\hline
\end{tabular}
\(\mathbf{B}_{\text {Binary }}\) : It is TSM-MWC, but the set \(B\) of branching vertices of Algorithm 1 is generated using only binary MaxSAT reasoning; i.e., the lines 3 and 4 of Algorithm 4 are removed.
\(\mathbf{B}_{I S}:\) It is \(\mathrm{B}_{\text {Binary }}\), but the set \(B\) of branching vertices of Algorithm 1 is generated using the standard IS partition approach as in WLMC and MWCLQ: Let \(v_{1}<\cdots<v_{n}\) be an ordering over the vertices of the input graph and let the colors be represented by positive integers. For \(i=n\) downto 1 , it assigns the smallest possible color to \(v_{i}\). An IS consists of the vertices with the same color.
\(\mathbf{B}_{\text {Ordered }}\) : It is \(\mathrm{B}_{I S}\), but the set \(B\) generated by the standard IS partition approach is further reduced using ordered MaxSAT reasoning (Algorithm 3). Unlike TSM-MWC, \(\mathrm{B}_{\text {Ordered }}\) does not use binary MaxSAT reasoning.
\(\mathbf{B}_{\text {MaxSAT }}\) : It is \(\mathrm{B}_{I S}\), but the set \(B\) generated by the standard IS partition approach is further reduced using brute-force MaxSAT reasoning as in WLMC, instead of using ordered MaxSAT reasoning as in TSM-MWC.
Table 5 compares the number of solved instances and the mean search tree size (in \(10^{5}\) ) of the four solvers using the graphs of Tables 1-3 and the same cutoff times. \(\mathrm{B}_{\text {Binary }}\) solves more DIMACS, massive and KES graphs than \(\mathrm{B}_{I S}\), and generates smaller search trees, showing that binary MaxSAT reasoning generates smaller sets of branching vertices than the common IS partition approach. Similarly, \(\mathrm{B}_{\text {Ordered }}\) solves more DIMACS, massive and KES graphs than \(\mathrm{B}_{\text {MaxSAT }}\) and its search trees are generally smaller, showing that ordered MaxSAT reasoning is more efficient than brute-force MaxSAT reasoning in reducing the number of branching vertices. Note that TSM-MWC implements both binary and ordered MaxSAT reasoning and is substantially better than the four variants in Table 5.

\section*{Conclusions}

We proposed TSM-MWC, a new exact algorithm for MWC that incorporates a novel two-stage MaxSAT reasoning approach to minimizing the number of branches: binary MaxSAT reasoning to generate an initial set of branching vertices and ordered MaxSAT reasoning to further reduce the number of branching vertices. The reported experiments show that the two-stage MaxSAT reasoning approach is very effective in reducing the search space, and that TSM-MWC outperforms relevant exact and heuristic MWC algorithms on
small/medium graphs, real-world massive graphs and graphs from practical applications of MWC.
